

WHAT IS CLAIMED IS:

1. A method for combining a data packet in a communication system, the method comprising the steps of:

5 receiving a transmission of said data packet to obtain a received packet;

demodulating said received packet to be stored in a first storage medium;

determining whether said received packet is a retransmitted packet according to predetermined criteria; and,

if so, combining said received packet with a previous packet stored in a second storage medium using a maximum ratio combining method.

10 2. The method of claim 1, wherein the step of determining whether said received packet is a retransmitted packet further comprises the steps of:

determining whether the length field of said received packet and said stored packet

15 are the same;

determining whether the retry bit field of said received packet is activated when the length field of said received packet and said stored packet are the same; and,

determining whether the sequence control field of said received packet and said stored packet are the same when the retry bit field of said received packet is activated.

3. The method of claim 1, wherein the step of determining whether said received packet is a retransmitted packet further comprises the step of determining whether the address field of said received packet and said stored packet are the same.

5 4. The method of claim 1, wherein the step of combining the received packet with said previous packet is performed according to the signal-to-noise ratio (SNR) symbol of said received packet and said stored packet.

10 5. The method of claim 1, wherein said predetermined criteria are based on a medium access control (MAC) frame of said received packet and said stored packet.

6. The method of claim 1, wherein the step of combining said received packet with said stored packet is performed in an access point (AP).

15 7. The method of claim 6, wherein the step of combining said received packet with said stored packet is performed in a mobile station in communication with said AP.

8. The method of claim 1, wherein the step of determining whether said received packet is a retransmitted packet further comprises the steps of:

20 determining whether the length field of said received packet and said previous packet are the same;

determining whether the retry bit field of said received packet is activated when the length field of said received packet and said previous packet are the same;

determining whether the address field of said received packet and said previous packet are the same when the retry bit field of said received packet is activated; and,

5 determining whether the sequence control field of said received packet and said previous packet are the same when the address field of said received packet and said previous packet are the same.

9. A method for combining a data packet in a communication system, the
10 method comprising the steps of:

 receiving and storing a transmission of said data packet in a first storage medium to
 obtain a received packet;

 extracting a physical layer convergence protocol (PLCP) and MAC header from
 said received packet stored in said first storage medium;

15 comparing the PLCP and MAC header of said data packet stored in said first storage
 medium and a previously received packet with error stored in a second storage medium to
 determine whether said received packet is said retransmitted packet; and,

 if so, combining said received packet with said previous packet stored in a second
 storage medium using a maximum ratio combining method.

10. The method of claim 9, wherein the step of combining the received packet with said previous packet is performed according to the signal-to-noise ratio (SNR) symbol of said received packet and said previous packet.

5 11. The method of claim 9, wherein the step of determining whether said received packet is said retransmitted packet further comprises the step of determining whether the address field of said received packet and said previous packet are the same.

10 12. The method of claim 9, wherein the step of determining whether said received packet is said retransmitted packet further comprises the steps of:

determining whether the length field of said received packet and said previous packet are the same;

determining whether the retry bit field of said received packet is activated when the length field of said received packet and said previous packet are the same; and,

15 determining whether the sequence control field of said received packet and said previous packet are the same when the retry bit field of said received packet is activated.

20 13. The method of claim 9, wherein the step of combining said received packet with said previous packet is performed in an access point (AP).

14. The method of claim 13, wherein the step of combining said received packet with said previous packet is performed in a mobile station in communication with said AP.

15. The method of claim 9, wherein the step of determining whether said received packet is said retransmitted packet further comprises the steps of:

determining whether the length field of said received packet and said previous packet are the same;

5 determining whether the retry bit field of said received packet is activated when the length field of said received packet and said previous packet are the same;

determining whether the address field of said received packet and said previous packet are the same when the retry bit field of said received packet is activated; and,

10 determining whether the sequence control field of said received packet and said previous packet are the same when the address field of said received packet and said previous packet are the same.

16. An apparatus for combining a data packet in a communication system, comprising:

15 a demodulation means for demodulating a transmission of said data to obtain a received packet;

a first storage means for storing said received packet;

a second storage means for storing a previous packet with error; and,

a processor for determining whether said received packet is a retransmitted packet

20 in response to said previous packet according to predetermined criteria; and,

a combining means for combining said received packet with said previous packet when said predetermined criteria is satisfied.

17. The apparatus of claim 16, further comprising at least one antenna for receiving the transmission of said data and said previous packet.

18. The apparatus of claim 16, wherein said combining means uses a maximum 5 ratio combining method.

19. The apparatus of claim 16, wherein said maximum combining method is performed according to the signal-to-noise ratio (SNR) symbol of said received packet and said previous packet.

20. The apparatus of claim 16, wherein said predetermined criteria are based on a medium access control (MAC) frame of said received packet and said previous packet.

21. The apparatus of claim 20, wherein said processor further operates to 15 determine that said received packet is a retransmitted packet when the length field of said MAC frame for said received packet and said previous packet are the same.

22. The apparatus of claim 16, wherein said processor further operates to 20 determine that said received packet is said retransmitted packet when the retry bit field of said MAC frame for said received packet is activated.

23. The apparatus of claim 16, wherein said processor further operates to determine that said received packet is said retransmitted packet when the address field of said MAC frame for said received packet and said previous packet are the same.

24. The apparatus of claim 16, wherein said processor further operates to determine that said received packet is said retransmitted packet when the sequence control field of said MAC frame for said received packet and said previous packet are the same.
